above 200 °F (95 °C)], they can subsequently crack when cooled back down to ambient.

g) Microstructure.

1. Blistering and HIC are strongly affected by the presence of inclusions and laminations, which provide sites for diffusing hydrogen to accumulate.

— Flat, elongated manganese sulfide (MnS) inclusions produced by ordinary steel plate rolling practices are particularly detrimental. However, steel chemical composition and manufacturing methods can be tailored to produce HIC-resistant steels. (See Reference 6.)

— Improving steel cleanliness and processing to minimize blistering and HIC damage may still leave the steel susceptible to SOHIC.

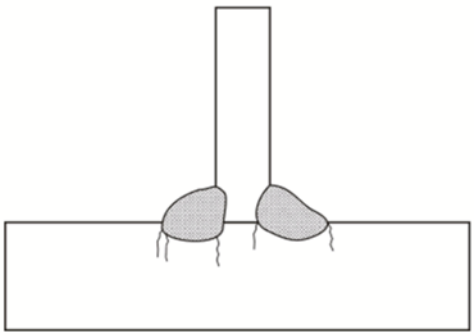
2. HIC is often found in so-called "dirty" steels with high levels of inclusions or other internal discontinuities from the steel-making process.

c) HIC-resistant steels can be used to minimize the susceptibility to blistering and HIC damage. Detailed materials and fabrication guidance can be found in Reference 6.

d) PWHT can help minimize susceptibility to SOHIC.

e) PWHT will not prevent blistering or HIC, because they are not initiated by stress and usually occur away from and not associated with welds.

f) SSC in welds can generally be prevented by limiting the hardness of carbon steel welds and HAZs to 200 HB maximum. Similar, but slightly higher, maximum hardness limits are normally applied to Cr-Mo steels for which high hardness is prevented by using preheat, PWHT, and welding procedure control.



Schematic of SOHIC damage at a fillet weld that is usually a combination of SSC and SOHIC.

6 Evaluation and definition of service conditions to enable material selection

6.1 Before selecting or qualifying materials using ANSI/NACE MR0175/ISO 15156-2 or ANSI/NACE MR0175/ISO 15156-3, the user of the equipment shall define, evaluate, and document the service conditions to which materials can be exposed for each application. The defined conditions shall include both intended exposures and unintended exposures that can result from the failure of primary containment or protection methods. Particular attention shall be paid to the quantification of those factors known to affect the susceptibility of materials to cracking caused by H_2S.

Factors, other than material properties, known to affect the susceptibility of metallic materials to cracking in H_2S service include H_2S partial pressure, *in situ* pH, the concentration of dissolved chloride or other halide, the presence of elemental sulfur or other oxidant, temperature, galvanic effects, mechanical stress, and time of exposure to contact with a liquid water phase.

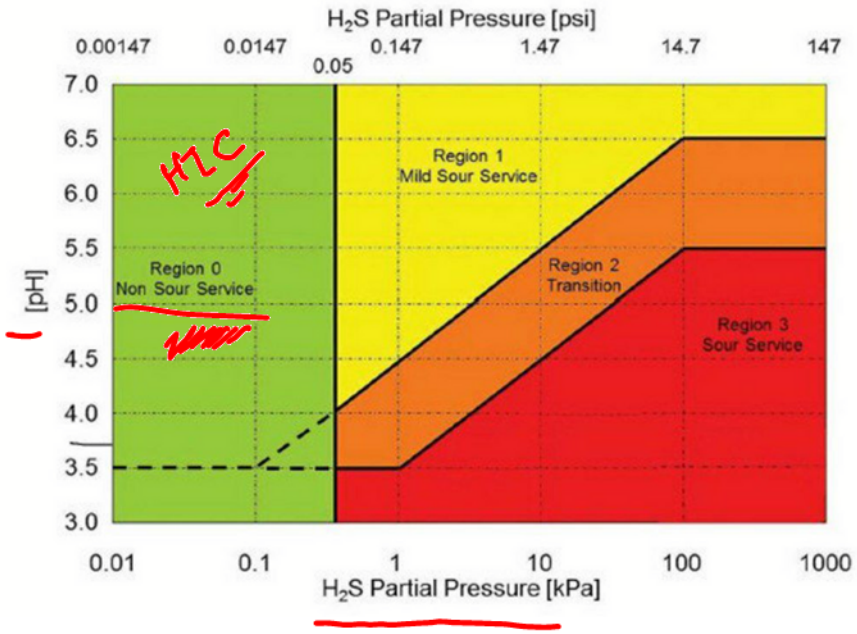
6.2 The documented service conditions shall be used for one or more of the following purposes:

a) to provide the basis for selection of SSC/SCC-resistant materials from existing lists and tables (see Clause 7);

b) to provide the basis for qualification and selection based upon documented field experience (see 8.2);

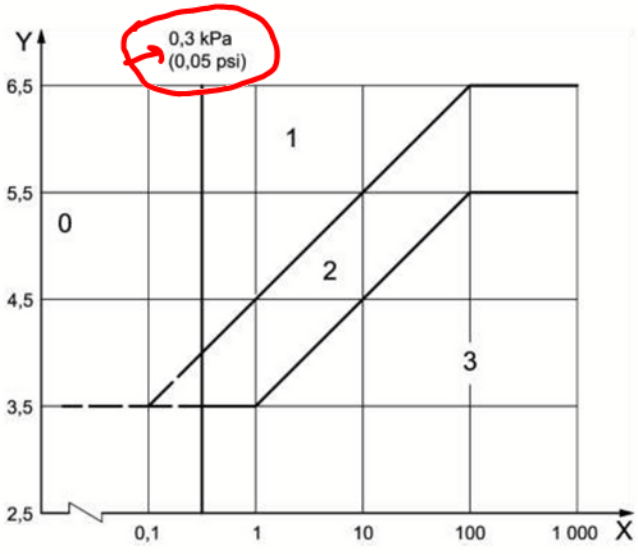
c) to define the laboratory test requirements to qualify a material for H_2S service with respect to one or more of SSC, SCC, HIC, SOHIC, SZC, and/or galvanically induced HSC (see 8.3);

d) to provide the basis for the reassessment of the suitability of existing alloys of construction, using Clause 7, 8.2, and/or 8.3, in the event of changes to the actual or intended service conditions.



7.2.1.2 SSC regions of environmental severity

The severity of the sour environment, determined in accordance with ANSI/NACE MR0175/ISO 15156-1, with respect to the SSC of a carbon or low-alloy steel shall be assessed using Figure 1. In defining the severity of the H_2S-containing environment, the possibility of exposure to unbuffered, condensed aqueous phases of low pH during upset operating conditions or downtime, or to acids used for well stimulation and/or the backflow of stimulation acid after reaction should be considered.



Key

X H_2S partial pressure, expressed in kilopascals
Y *in situ* pH
0 region 0
1 SSC region 1
2 SSC region 2
3 SSC region 3

NOTE 1 The discontinuities in the figure below 0.3 kPa (0.05 psi) and above 1 MPa (150 psi) partial pressure H_2S reflect uncertainty with respect to the measurement of H_2S partial pressure (low H_2S) and the steel's performance outside these limits (for both low and high H_2S).

ANSI/NACE MR0175/ISO 15156-2:2015(E)

7.2.1.3 Region 0 — For p_{H_2S} < 0.3 kPa (0.05 psi)

Normally, no precautions are required for the selection of steels for use under these conditions. Nevertheless, a number of factors, as follows, that can affect a steel's performance in this region should be considered.

— Steels that are highly susceptible to SSC and HSC can crack.

— Steel's physical and metallurgical properties affect its inherent resistance to SSC and HSC; see Clause 6.

— Very high-strength steels can suffer HSC in aqueous environments without H_2S. Above about 965 MPa (140 ksi) yield strength, attention should be given to steel composition and processing to ensure that these steels do not exhibit SSC or HSC in region 0 environments.

— Stress concentrations increase the risk of cracking.

7.2.1.4 SSC regions 1, 2 and 3

Referring to the regions of severity of the exposure as defined in Figure 1, steels for region 1 may be selected using A.2, A.3 or A.4; steels for region 2 may be selected using A.2 or A.3; and steels for region 3 may be selected using A.2.

In the absence of suitable choices from Annex A, carbon and low-alloy steels may be tested and qualified for use under specific sour-service conditions or for use throughout a given SSC region. Testing and qualification shall be in accordance with ANSI/NACE MR0175/ISO 15156-1 and Annex B.

Documented field experience may also be used as the basis for material selection for a specific sour-service application; see ANSI/NACE MR0175/ISO 15156-1.

6 Factors affecting the behaviour of carbon and low alloy steels in H_2S-containing environments

The behaviour of carbon and low-alloy steels in H_2S-containing environments is affected by comple interactions of parameters, including the following:

a) chemical composition, method of manufacture, product form, strength, hardness of the material and its local variations, amount of cold work, heat-treatment condition, microstructure, microstructural uniformity, grain size and cleanliness of the material;

b) H_2S partial pressure or equivalent concentration in the water phase;

c) chloride ion concentration in the water phase;

d) acidity (pH) of the water phase;

e) presence of sulfur or other oxidants;

f) exposure to non-production fluids;

g) exposure temperature;

h) total tensile stress (applied plus residual);

i) exposure time.

These factors shall be considered when using this part of ANSI/NACE MR0175/ISO 15156 for the selection of materials suitable for environments containing H_2S in oil and gas production systems.

7 Qualification and selection of carbon and low-alloy steels with resistance to SSC, SOHIC and SZC

7.1 Option 1 — Selection of SSC-resistant steels (and cast irons) using A.2

7.1.1 For p_{H_2S} < 0.3 kPa (0.05 psi)

The selection of materials for SSC resistance for p_{H_2S} below 0.3 kPa (0.05 psi) is not considered in detail in this part of ANSI/NACE MR0175/ISO 15156. Normally, no special precautions are required for the selection of steels for use under these conditions, nevertheless, highly susceptible steels can crack. Additional information on factors affecting susceptibility of steels and attack by cracking mechanisms other than SSC is given in 7.2.1.

7.1.2 For p_{H_2S} ≥ 0.3 kPa (0.05 psi)

If the partial pressure of H_2S in the gas is equal to or greater than 0.3 kPa (0.05 psi), SSC-resistant steels shall be selected using A.2.

NOTE 1 The steels described or listed in A.2 are considered resistant to SSC in oil and natural-gas production and natural-gas treatment plants.

NOTE 2 Users concerned with the occurrence of SOHIC and/or SZC can refer to Option 2 (see 7.2.2).

NOTE 3 For HIC and SWC, see Clause 8.

7.2 Option 2 — Selection of steels for specific sour-service applications or for ranges of sour service

ANSI/NACE MR0175/ISO 15156-2:2015(E)

Annex A
(normative)

SSC-resistant carbon and low alloy steels (and requirements and recommendations for the use of cast irons)

A.1 General

This annex describes and lists SSC-resistant carbon and low alloy steels. Requirements for the use of cast irons are given in A.2.4.

Steels complying with this annex might not resist SOHIC, SZC, HIC or SWC without the specification of additional requirements (see 7.2.2 and/or Clause 8).

NOTE A.2 is consistent with the previously established requirements of NACE MR0175.

At the time of publication of this part of ANSI/NACE MR0175/ISO 15156, there are no listings of steels approved for SSC region 2 (A.3) or SSC region 1 (A.4). Therefore, A.3 and A.4 indicate only properties typical of steels that are expected to be suitable for use under the defined conditions.

A.2 SSC-resistant carbon and low-alloy steels and the use of cast irons

A.2.1 General requirements for carbon and low alloy steels

A.2.1.1 General

Carbon and low-alloy steels shall comply with A.2.1.2 through A.2.1.9.

Carbon and low-alloy steels, products and components that comply with A.2 are, with stated exceptions, qualified in accordance with this part of ANSI/NACE MR0175/ISO 15156 without further SSC testing. Nevertheless, any SSC testing that forms part of a materials manufacturing specification shall be carried out successfully and the results reported.

The majority of steels that comply with the general requirements of A.2 are not individually listed; however, for convenience, some examples of such steels are listed in Table A.2, Table A.3 and Table A.4.

NOTE 1 The carbon and low-alloy steels described/listed previously in NACE MR0175 (all revisions) were identified by extensive correlations of field failures/successes and laboratory data. The hardness limit of HRC 22 applied to most carbon and low-alloy steels is based on correlations of heat treatment, chemical composition, hardness and failure experience. The higher hardness limits for the chromium-molybdenum steels are based on similar considerations.

NOTE 2 It can be possible to qualify a carbon or low alloy steel not described or listed in the text or tables of A.2 for use in specific sour service applications or for a range of sour service in accordance with Option 2 (7.2).

A.2.1.4 Welding

Welding and weld-hardness determinations shall be performed in accordance with 7.3.3.

Acceptable maximum hardness values for carbon steel, carbon manganese steel and low alloy steel welds are given in Table A.1.

As-welded carbon steels, carbon-manganese steels and low-alloy steels that comply with the hardness requirements of Table A.1 do not require post-weld heat treatment.

Tubular products with an SMYS not exceeding 360 MPa (52 ksi) and listed in Table A.2 are acceptable in the as-welded condition. For these products, hardness testing of welding procedures may be waived if agreed by the equipment user.

Some tubular products with an SMYS exceeding 360 MPa (52 ksi) (see A.2.2.2) may be acceptable in the as-welded condition if suitable qualified welding procedures are used. The conditions in Table A.1 shall be met.

Carbon steel, carbon manganese and low-alloy steel weldments that do not comply with other paragraphs of this subclause shall be post weld heat treated after welding. The heat treatment temperature and its duration shall be chosen to ensure that the maximum weld zone hardness, determined in accordance with 7.3, shall be 250 HV or, subject to the restrictions described in 7.3.3, 22 HRC.

A minimum post weld heat treatment temperature of 620 °C (1 150 °F) shall be used for low alloy steels.

The acceptability of any effects on mechanical properties, other than hardness, caused by the chosen heat treatment and its duration shall be subject to the approval of the equipment user.

Welding consumables and procedures that produce a deposit containing more than 1 % mass fraction nickel are acceptable after successful weld SSC qualification by testing in accordance with Annex B.

ادامه
A.2.1.4 ادامه جوش

A.2.1.4 Welding

Welding and weld-hardness determinations shall be performed in accordance with 7.3.3.

Acceptable maximum hardness values for carbon steel, carbon manganese steel and low alloy steel welds are given in Table A.1.

As-welded carbon steels, carbon-manganese steels and low-alloy steels that comply with the hardness requirements of Table A.1 do not require post-weld heat treatment.

Tubular products with an SMYS not exceeding 360 MPa (52 ksi) and listed in Table A.2 are acceptable in the as-welded condition. For these products, hardness testing of welding procedures may be waived if agreed by the equipment user.

Some tubular products with an SMYS exceeding 360 MPa (52 ksi) (see A.2.2.2) may be acceptable in the as-welded condition if suitable qualified welding procedures are used. The conditions in Table A.1 shall be met.

Carbon steel, carbon manganese and low-alloy steel weldments that do not comply with other paragraphs of this subclause shall be post weld heat treated after welding. The heat treatment temperature and its duration shall be chosen to ensure that the maximum weld zone hardness, determined in accordance with 7.3, shall be 250 HV or, subject to the restrictions described in 7.3.3, 22 HRC.

A minimum post weld heat treatment temperature of 620 °C (1 150 °F) shall be used for low alloy steels.

The acceptability of any effects on mechanical properties, other than hardness, caused by the chosen heat treatment and its duration shall be subject to the approval of the equipment user.

Welding consumables and procedures that produce a deposit containing more than 1 % mass fraction nickel are acceptable after successful weld SSC qualification by testing in accordance with Annex B.

جدول A.1 - حداکثر سختی جوش MR0175-2

Table A.1 — Maximum acceptable hardness values for carbon steel, carbon-manganese steel and low-alloy steel welds

Hardness test methods	Hardness test locations for welding procedure qualification	Maximum acceptable hardness

A.2.1.6 Cold deformation and thermal stress relief PFHT-

Carbon and low-alloy steels shall be thermally stress-relieved following any cold deforming by rolling, cold forging or other manufacturing process that results in a permanent outer fibre deformation greater than 5 %. Thermal stress relief shall be performed in accordance with an appropriate code or standard. The minimum stress-relief temperature shall be 595 °C (1 100 °F). The final maximum hardness shall be 22 HRC except for pipe fittings made from ASTM A234 grade WPB or WPC, for which the final hardness shall not exceed 197 HBW.

Wet H2S → %Fe > 5% → PFHT → applicable code

→ UCS-56 / 331.1.1 } → Min Hold = 595°C → Hardness 22 HRC
Tam

A2.1.6

ANSI/NACE MR0175/ISO 15156-2:2015(E)

The above requirement does not apply to cold work imparted by pressure testing according to an applicable code or standard agreed by the equipment user.

Cold-rotary straightened pipe is acceptable only where permitted in the applicable ISO or API product standards; see also A.2.2.3.4.

Cold-worked line pipe fittings of ASTM A53 Grade B, ASTM A106 Grade B, API 5L Grade X-42, ISO 3183 Grade L290, or lower-yield-strength grades with similar chemical compositions, are acceptable with cold strain equivalent to 15 % or less, provided the hardness in the strained area does not exceed 190 HBW.

SSC testing and qualification in accordance with Annex B may be used to justify other cold deformation limits.

A53 Gr.B / API 5L X42 – ≤ 15% ~ 190 HBW

نکات مهم در MR0175 :

۱- آیا سختی 22 HRC به عنوان معیار انتخاب MR0175 است؟ خیر

۲- آیا ناحیه صفر (Region 0 P_{H_2S} < 0.05 psi) به عنوان ناحیه کاملا ایمن محسوب میشود؟ خیر

۳- آیا در MR0175 بودن یا نبودن H2S موضوع MR0103 - خیر؟

Sp0296
Tm0284

Sp0472
P1 – MR0103

۴) آیا الزامات استاندارد ISO 15156 یا NACE MR0175 لحاظ شده است؟ بله

۵) آیا منزوی دیافراگم کوره برای تنش گیری مطابق NACE کنترل می شود؟ خیر

۶) آیا جوشکاری نیاز به PWHT دارد؟ خیر

۷) آیا از متریال استوک قبل 2003 می توانیم بدون تنش گیری استفاده نماییم (بر اساس Clause 7) ؟ خیر

۸) آیا می توان از سختی سنجی پرتابل استفاده نمود؟ Leeb

بله – البته با رعایت شرایط زیر

۱- ISO 16859-1 و حداکثر زبری میانگین $Ra < 2\ \mu m$

۲- رعایت الزامات بند 7.3.3.2

7.3.3.2 Hardness testing methods for welding procedure qualification

Hardness testing for welding procedure qualification shall normally be carried out using the Vickers HV 10 or HV 5 method in accordance with ISO 6507-1, or the Rockwell method in accordance with ISO 6508-1 using the 15N scale.

NOTE For the purposes of this provision, ASTM E384 is equivalent to ISO 6507-1 and ASTM E18 is equivalent to ISO 6508-1.

HRC بدون PWHT

The HRC method may be used for welding procedure qualification if the design stress does not exceed two-thirds of SMYS and the welding procedure specification includes post-weld heat treatment. The use of the HRC method for welding procedure qualification in all other cases shall require the agreement of the equipment user.

NOTE Hardness surveys using the Vickers or Rockwell 15N testing method produce a more detailed picture of weld hardness and its variations. Hardness surveys using the HRC testing method might not detect small zones in welds or HAZs where the hardness exceeds the acceptance criteria for the Vickers or Rockwell 15N testing method. The significance of such small hard zones is not well understood.

The use of other hardness testing methods shall require the agreement of the equipment user.

The Vickers or Rockwell 15N hardness testing method shall be used for the qualification of alternative weld-hardness acceptance criteria as permitted in 7.3.3.4.

8 SCC DF—Sulfide Stress Cracking (SSC)

8.1 Scope

The DF calculation for components subject to SSC is covered in this section.

8.2 Description of Damage

SSC is defined as cracking of a metal under the combined action of tensile stress and corrosion in the presence of water and hydrogen sulfide. SSC is a form of HSC resulting from absorption of atomic hydrogen that is produced by the sulfide corrosion process on the metal surface. SSC usually occurs more readily in high strength (high hardness) steels in hard weld deposits or hard heat-affected zones (HAZs) of lower-strength steels. Susceptibility to SSC is related to the hydrogen permeation flux in the steel, which is primarily associated with two environmental parameters, pH and H_2S content of the water. Typically, the hydrogen flux in steels has been found to be lowest in near neutral pH solutions, with increasing flux at both lower and higher pH values. Corrosion at low pH values is caused by H_2S, whereas corrosion at high pH values is caused by high concentrations of the bisulfide ion. Presence of cyanides at elevated pH can further aggravate the hydrogen penetration into the steel. SSC susceptibility is known to increase with H_2S content, e.g. H_2S partial pressure in the gas phase or H_2S content of the water phase. The presence of as little as 1 ppm of H_2S in the water has been found to be sufficient to cause SSC.

Table 8.2—Environmental Severity—SSC

pH of Water	Environmental Severity As a Function of H_2S Content of Water			
	<50 ppm	50 to 1,000 ppm	1,000 to 10,000 ppm	>10,000 ppm
<5.5	Low	Moderate	High	High
5.5 to 7.5	Low	Low	Low	Moderate
7.6 to 8.3	Low	Moderate	Moderate	Moderate
8.4 to 8.9	Low	Moderate	Moderate [1]	High [1]
>9.0	Low	Moderate	High [1]	High [1]

NOTE 1 If cyanides are present, increase the susceptibility to SSC one category for pH > 8.3 and H_2S concentrations greater than 1,000 ppm.

Table 8.3—Susceptibility to SSC—SSC

International Standard

ANSI/NACE MR0103/ISO 17495-1:2016

Petroleum, petrochemical and natural gas industries — Metallic materials resistant to sulfide stress cracking in corrosive petroleum refining environments

حسنه کاربری

Petroleum, petrochemical and natural gas industries — Metallic materials resistant to sulfide stress cracking in corrosive petroleum refining environments

1 Scope

This International Standard establishes material requirements for resistance to SSC in sour petroleum refining and related processing environments containing H_2S either as a gas or dissolved in an aqueous (liquid water) phase with or without the presence of hydrocarbon. This International Standard does not include and is not intended to include design specifications. Other forms of wet H_2S cracking, environmental cracking, corrosion, and other modes of failure are outside the scope of this International Standard. It is intended to be used by refiners, equipment manufacturers, engineering contractors, and construction contractors.

Specifically, this International Standard is directed at the prevention of SSC of equipment (including pressure vessels, heat exchangers, piping, valve bodies, and pump and compressor cases) and components used in the refining industry. Prevention of SSC in carbon steel categorized under P-No. 1 in Section IX of the ASME Boiler and Pressure Vessel Code (BPVC) is addressed by requiring compliance with NACE SP0472.

This International Standard applies to all components of equipment exposed to sour refinery environments (see Clause 6) where failure by SSC would (1) compromise the integrity of the pressure-containment system, (2) prevent the basic function of the equipment, and/or (3) prevent the equipment from being restored to an operating condition while continuing to contain pressure.

NACE Standard SP0296-2016
Item No. 21078

Approved March 2016

Detection, Repair, and Mitigation of Cracking in Refinery Equipment in Wet H_2S Environments

5 Responsibilities

5.1 Responsibilities of the end user

5.1.1 It is the responsibility of the end user (or the end user's agent) to determine the operating conditions and to specify when this International Standard applies.

5.2 Responsibility of the manufacturer

The manufacturer is responsible for meeting the metallurgical requirements of this International Standard.

6 Factors contributing to SSC

6.1 General parameters affecting SSC

SSC in refining equipment is affected by complex interactions of parameters including the following:

a) chemical composition, strength (as indicated by hardness), heat treatment, and microstructure of the material exposed to the sour environment;

b) total tensile stress present in the material (applied plus residual);

c) hydrogen flux generated in the material, which is a function of the environment (i.e. presence of an aqueous phase, H_2S concentration, pH, and other environmental parameters such as bisulfide ion concentration and presence of free cyanides);

d) temperature;

e) time.

6.2 - متریال و سطح تنش

6.2 Effect of material condition and stress level on susceptibility to SSC

6.2.1 Material susceptibility to SSC is primarily related to material strength (as indicated by hardness), which is affected by chemical composition, heat treatment, and microstructure. Materials with high hardness generally have an increased susceptibility to SSC.

6.2.2 SSC has not generally been a concern for carbon steels typically used for refinery pressure vessels and piping in wet H_2S service because these steels have sufficiently low hardness levels.

6.2.3 Improperly heat-treated metals, weld deposits, and heat-affected zones (HAZ), however, may contain regions of high hardness.

6.2.4 Susceptibility for a given material increases with increased tensile stress.

6.2.5 Residual stresses contribute to the overall tensile stress level. High residual stresses associated with welds increase susceptibility to SSC.

6.2.6 Control of weldment hardness, with or without reduction of residual stresses, is a recognized method for preventing SSC, as outlined in NACE SP0472 for P-No. 1 carbon steels.

6.2 قدرت نفوذ هیدروژن:

دو عامل اصلی تعیین کننده

PH

میزان حد پسماند فولادی

آنالیز A

عنوان Ar

رابطه PH- =

6.3 Effect of hydrogen permeation flux on SSC

6.3.1 Susceptibility to SSC is also related to the hydrogen permeation flux in the steel, which is primarily associated with two environmental parameters: pH and total sulfide content of the aqueous phase. In a closed system at equilibrium condition, dissolved hydrogen sulfide (H_2S_{aq}), bisulfide ion (HS^-), and sulfide ion (S^{2-}) (sometimes called "soluble sulfide") exist in an aqueous solution in different pH ranges.

6.3.2 The sulfide species plot exhibited in Figure A.1 shows their relative amounts present in an aqueous solution at 25 C (77°F) as a function of pH. At pH less than 6, H_2S_{aq} is the dominant (>90 % of total) sulfide specie present in the aqueous phase. At pH between 8 and 11, the dominant (>90 % of total) sulfide specie present in the aqueous phase is HS^-. At pH greater than 13, the dominant (>90 % of total) sulfide specie present in the aqueous phase is S^{2-}. At pH 7, the system contains 50 % H_2S_{aq}, 50 % HS^-, and virtually no S^{2-}. At pH 12, the system contains 50 % HS^-, 50 % S^{2-}, and virtually no H_2S_{aq}. The total sulfide content, therefore, refers to the total amount of all three sulfide species present in the aqueous phase (i.e. the sum of H_2S_{aq}, HS^-, and S^{2-}).

6.3.3 Typically, the hydrogen flux in steels has been found to be lowest in near-neutral pH solutions, with increasing flux at both lower and higher pH values. Corrosion at lower pH values is typically caused by H_2S_{aq}, whereas corrosion at higher pH values is typically caused by high concentrations of HS^-.

6.3.4 In many refinery sour water environments, the presence of dissolved ammonia (NH_3) increases the pH, thereby increasing the solubility of H_2S and resulting in a high HS^- concentration. At elevated pH, the presence of free cyanides, which include dissolved hydrogen cyanide (HCN_{aq}) and cyanide ion (CN^-), can further aggravate the degree of atomic hydrogen charging into the steel. Even though SSC susceptibility is known to increase with total sulfide content of the aqueous phase, the presence of as little as 1 ppmw total sulfide in the aqueous phase can cause SSC under conditions that promote aggressive hydrogen charging.

6.3.5 For carbon steel, some environmental conditions known to cause SSC are those containing an aqueous (liquid water) phase and either of the following:

a) >50 ppmw total sulfide content in the aqueous phase;

b) ≥1 ppmw total sulfide content in the aqueous phase and pH < 4;

c) ≥1 ppmw total sulfide content and ≥20 ppmw free cyanide in the aqueous phase, and pH > 7,6;

d) >0,3 kPa absolute (0,05 psia) partial pressure H_2S in the gas phase associated with the aqueous phase of a process.

6.3.6 The high-pH sour environments differentiate refinery sour service from the oil and gas production sour environments covered by NACE MR0175/ISO 15156, because many wet sour streams in oil and gas production also contain carbon dioxide and, hence, exhibit a lower pH. Another major difference is that chloride ion concentrations tend to be significantly lower in refinery sour services than in oil production sour services.

1 H_2S_{aq}
2 HS^-
3 S^{2-}
X pH
Y mole fraction of sulfur species

Figure A.1 — Sulfide species plot for closed system at 25 °C (77 °F)

6.4 Effect of elevated temperature exposure on SSC

The hydrogen charging potential increases with increasing temperature provided the aqueous phase is not eliminated by the elevated temperature. Elevated temperature promotes dissociation of H_2S (thereby producing more monatomic hydrogen), and increases the diffusion rates of monatomic hydrogen in metals, thereby promoting hydrogen charging. However, cracking potential is maximized at near-ambient temperature. This distinction is important because metals can become charged during high-temperature exposure and subsequently crack during excursions to lower temperatures (such as during shutdowns).

6.5 - فاکتورهای تاثیرگذار بر زمان تخریب

6.5 Factors affecting time to failure due to SSC

The time to failure decreases as material strength, total tensile stress, and environmental charging potential increase. Exposure time to cause SSC can be very short, if the other SSC factors favour susceptibility. Some susceptible equipment can fail even during short sour water excursions such as those encountered during equipment shutdowns.

7 Materials included in this International Standard

7.1 Materials included in this International Standard are resistant to, but not necessarily immune to, SSC. Materials have been included based on their demonstrated resistance to SSC in field applications, in SSC laboratory testing, or both.

7.2 Listed materials do not all exhibit the same level of resistance to SSC. Standard laboratory SSC tests, such as those addressed in NACE Standard TM0177, are accelerated and severe tests. Materials that successfully pass these tests are generally more resistant to cracking in sour service than materials that fail the tests. Many alloys included in this International Standard perform satisfactorily in sour service even though they may crack in laboratory tests.

7.3 Improper design, processing, installation, or handling can cause resistant materials to become susceptible to SSC.

7.4 No effort has been made in this International Standard to rank materials based on their relative resistance to SSC. Selection of the appropriate material for a given application depends on a number of factors, including mechanical properties, corrosion resistance, and relative resistance to SSC, and is beyond the scope of this International Standard.

7.5 There are a number of instances where this International Standard specifically references the ASME BPVC. There are other instances where this International Standard references specific industry standards and/or designations for material grades, conditions, and testing requirements (e.g. ASTM, NACE, API, and UNS numbers). In these cases, the use of alternate "equivalent" standards, grade designations, condition designations, or testing methods shall only be permitted when approved by the end user. It is the responsibility of the agency requesting the substitution to provide to the end user sufficient information, data, etc. in order to prove "equivalency." If it is not clear that an alternate standard, grade designation, and/or condition designation is identical to the standard, grade

8 Hardness requirements

8.1 Hardness is related to tensile strength, a primary factor in SSC susceptibility. Because hardness testing is non-destructive and requires relatively minor component/specimen preparation compared with tensile testing, it is commonly used by manufacturers in production quality control and by users in field inspection. As such, a maximum allowable hardness is specified as a primary requirement for many of the materials in this International Standard.

8.2 Several different hardness scales are used in this International Standard. The most commonly used scales are Rockwell "C" (HRC), Rockwell "B" (HRBS), Brinell (HBW), and Vickers 49 N (5 kgf) or 98 N (10 kgf) (HV 5 or HV 10). Background information on these hardness scales and the logic behind the various references is provided in Annex B.

8.3 Hardness testing and reporting shall be performed in strict compliance with the methods described in the appropriate ASTM or ISO standards. Annex B lists the appropriate standards for the various test methods.

8.4 The standard test parameters (indenters, loads, and major-load dwell time) shall be used for all Rockwell hardness tests. The specimen temperature for Rockwell hardness testing shall be 10 °C to 35 °C (50 °F to 95 °F). No lubricant shall be used. Because Brinell hardness tests are only indicated for steel materials in this International Standard, all Brinell hardness tests shall be performed using 29,4 kN (3 000 kgf) load, a 10 mm indenter, and the standard dwell time of 10 s to 15 s.

8.5 In some cases, maximum allowable hardness values are provided in both HRC (or HRBS) and HBW. In those instances, either scale may be used.

8.6 When hardness requirements are stated in HBW, and testing using stationary Brinell hardness equipment is not viable, testing shall be performed using the comparison hardness test method (commonly, but incorrectly, referred to as portable Brinell hardness testing).

8.7 When applicable, the conversion tables in ASTM E140 or ISO 18265 shall be used for conversion of hardness values obtained by other test methods to HRC, HRBS, or HBW values. However, tables for many materials do not exist in those standards. The tables should be used only for materials that are specifically listed. Conversions may be performed based on empirical data for materials that are not covered when approved by the end user. When converted hardness values are used, they shall be reported in accordance with the requirements specified in ASTM E140 or ISO 18265.

8.8 Sufficient hardness tests shall be made to establish the actual hardness of the material being examined. Individual hardness readings exceeding the specified value shall be considered acceptable if the average of several readings taken within close proximity does not exceed the specified value and no individual reading exceeds the specified value by more than 2 HRC (or by more than 5 % in the case of HBW or HV 10).

8.9 Acceptance criteria for microhardness testing using Knoop or Vickers hardness test methods (see ASTM E384) are outside the scope of this International Standard. See Annex B for more information.

8.10 The use of portable hardness testing methods to verify compliance with the requirements of this International Standard is prohibited unless explicitly approved by the end user. The one exception that does not require end user approval is the use of comparison hardness testing in accordance with ASTM A833 to evaluate weld deposits as specified in NACE SP0472 (see Annex B).

9 Procedure for the addition of new materials or processes

9.1 General balloting requirements

New materials and/or processes may be balloted based on field experience and/or laboratory test data.

9.2 Field experience data requirements

9.2.1 Field experience data shall document the alloy composition(s), condition(s), and hardness level(s), the process fluid parameters that influence SSC, and the exposure history.

9.2.2 In certain alloy families (such as duplex stainless steels), microstructure is also a critical variable, and shall also be documented.

9.3 Laboratory test data requirements

9.3.1 The laboratory testing of materials shall be performed in accordance with NACE Standard TM0177. If actual service conditions are outside these limits, SSC of approved materials may be possible.

9.3.2 The candidate material shall be tested in accordance with the test procedures established in NACE Standard TM0177. The tensile bar, C-ring, bent beam, and double-cantilever beam test specimens described in NACE Standard TM0177 are accepted test specimens. Any of these test specimens may be used.

9.3.3 A minimum of three test specimens from each of three different commercially prepared heats shall be tested in the condition balloted for inclusion. The composition of each heat and the heat treatment(s) used shall be furnished as part of the ballot. The candidate material's composition range and/or UNS number and its heat-treated condition requested for inclusion in this International Standard shall be included with the ballot.

13 Ferrous materials

13.1 Carbon and alloy steels

13.1.1 Requirements for all carbon and alloy steels

Carbon and alloy steels shall require the following:

a) not contain intentional additions of elements such as lead, selenium, or sulfur to improve machinability;

b) meet the criteria of 13.1.6 through 13.1.9;

c) be used in one of the following heat-treatment conditions:

1) hot-rolled (carbon steels only);
2) annealed;
3) normalized;
4) normalized and tempered;
5) normalized, austenitized, quenched, and tempered;
6) austenitized, quenched, and tempered.

NOTE There is no 1 % maximum nickel restriction for carbon steels and alloy steels.

13.1.2 Requirements for carbon steels listed as P-No. 1 Group 1 or 2 in Section IX of the ASME BPVC

13.1.2.1 Carbon steels listed as P-No. 1 Group 1 or 2 materials in Section IX of the ASME BPVC shall meet one of the conditions listed in 13.1.1, c). Base-metal hardness controls are not required.

13.1.2.2 Welding of P-No. 1 carbon steels shall be controlled in accordance with 13.1.7 and 13.1.9.

13.1.2.3 Bends in P-No. 1 piping formed by heating to above the upper transformation temperature, A_{c3}, are allowed. The material shall have met one of the conditions listed in 13.1.1, c) prior to forming. The hardness in the bend area shall not exceed 225 HBW.

13.1.2.4 Weld repairs in P-No. 1 castings shall be performed in accordance with the welding requirements specified in 13.1.7.

13.1.3 Requirements for other carbon steels

Other carbon steels shall have a maximum hardness of 22 HRC (237 HBW).

13.1.4 Requirements for alloy steels listed with P-numbers in Section IX of the ASME BPVC

Alloy steels included under the ASME BPVC Section IX P-numbers listed in Table 2 shall not exceed the indicated maximum hardness levels.

Table 2 — Maximum hardness requirements for P-Numbered alloy steels

Alloy steel	Maximum hardness
P-No. 3	225 HBW
P-No. 4	225 HBW
P-No. 5A	235 HBW
P-No. 5B	235 HBW
P-No. 5C	235 HBW
P-No. 6	235 HBW
P-No. 7	235 HBW
P-No. 10A	225 HBW
P-No. 10B	225 HBW
P-No. 10C	225 HBW
P-No. 10F	225 HBW
P-No. 11	225 HBW

13.1.5 Requirements for other alloy steels

Other alloy steels shall have a maximum hardness of 22 HRC (237 HBW).

13.1.6 Requirements for cold-formed carbon and alloy steels

13.1.6.1 Cold forming of carbon and alloy steels is allowed. The material shall have met one of the conditions listed in 13.1.1 c) prior to cold forming. Cold-formed material shall be thermally stress relieved following any cold deforming by rolling, cold forging, or another manufacturing process that results in a permanent outer fibre deformation greater than 5 %. Hydraulically formed materials shall be thermally stress relieved regardless of the percent outer fibre deformation.

13.1.6.2 Thermal stress relief shall be performed in accordance with the applicable ASME codes, except that the minimum stress-relief temperature shall be 593 °C (1 100 °F). After stress relieving, carbon steels listed as P-No. 1 materials in Section IX of the ASME BPVC shall meet a hardness requirement of 200 HBW maximum. Other carbon and alloy steels shall meet the appropriate hardness requirements in accordance with 13.1.3, 13.1.4, or 13.1.5.

13.1.6.3 Cold-rotary straightened pipe is allowed only when permitted in API specifications. Cold-worked line pipe fittings of ASTM A53 Grade B, ASTM A106 Grade B, API Spec 5L Grade X-42, or lower-strength grades with similar chemical compositions shall contain no more than 15 % cold strain, and the hardness in the strained area shall not exceed 190 HBW.

13.1.6.4 The requirements for cold forming stated above do not apply to pressure testing in accordance with the applicable code.

13.1.7 Welding requirements for carbon steels listed as P-No. 1 in Section IX of the ASME BPVC

13.1.7.1 Welding shall be performed in accordance with the general requirements listed in 15.3.

13.1.7.2 Weldments in carbon steels listed as P-No. 1 materials in Section IX of the ASME BPVC shall be produced using one or more of the methods outlined in NACE SP0472 to prevent excessive weldment hardness.

13.1.8 Welding requirements for alloy steels listed as P-No. 3, 4, or 5A in Section IX of the ASME BPVC

Some industry codes (such as ASME B31.3 and ANSI/NB-23) allow welding of P-No. 3, P-No. 4, and P-No. 5A alloy steels without PWHT in certain circumstances. Non-PWHT procedures of this type may be used provided a hardness survey in accordance with Annex C has been performed on a specimen taken from the welding procedure qualification test (WPQT) coupon(s) to demonstrate the ability of the procedure to produce weldments that meet the specified hardness limits. No individual hardness reading shall exceed 248 HV 10. Other alloy steel materials shall always receive PWHT when this International Standard applies to ensure low hardness in the weld deposit and HAZ. When PWHT is performed, a hardness survey in accordance with Annex C shall be performed on a specimen taken from the WPQT coupon(s) to demonstrate the ability of the PWHT time and temperature to produce weldments that meet the specified hardness limits. No individual hardness reading shall exceed 248 HV 10.

13.1.9 Corrosion resistant weld overlays, hard facing weld overlays, cladding, and thermal spray coatings on carbon steels and alloy steels

13.1.9.1 Overlays and cladding applied to carbon and alloy steels for use in sour environments shall meet the requirements listed in 15.2 and 15.4 and in 13.1.9.2 to 13.1.9.5.

13.1.9.2 When applied to P-No. 1 carbon steels, partial weld overlays that do not qualify as cladding in accordance with 3.6 shall be applied in such a way that the process-contacted interface between the overlay and the base metal has a HAZ and base metal hardness within the specified limits. Methods used to control the HAZ and base metal hardness, and acceptance criteria, shall be in accordance with NACE SP0472.

13.1.9.3 When applied to alloy steels or to carbon steels not P-Numbered in Section IX of the ASME BPVC, partial weld overlays shall be applied in such a way that the process-contacted interface between the overlay and base metal has a HAZ and base metal hardness within the specified limits. Hardness testing and acceptance criteria shall be in accordance with the limits provided in 13.1.3 through 13.1.5 and/or 13.1.8, as appropriate.

13.1.9.4 When thermal spray coatings are applied to P-No. 1 carbon steel materials in such a manner that any portion of the base metal exceeds the lower transformation temperature (A_{c1}) (e.g. in the case of a spray and fuse coating), the procedures used shall be qualified in accordance with NACE SP0472 requirements to ensure that the HAZ and base metal exhibit hardness within the spcified limits.

13.1.9.5 When thermal spray coatings are applied to alloy steels or to carbon steels not P-Numbered in Section IX of the ASME BPVC, in such a manner that any portion of the base metal exceeds the lower transformaton temperature (A_{c1}) (e.g. in the case of a spray and fuse coating), the procedure used shall be qualified with postweld heat treatment (PWHT) to ensure that the HAZ and base metal exhibit hardness within the specified limits. PWHT, hardness testing, and acceptance criteria shall be in accordance with limits provided in 13.1.3 through 13.1.5 and/or 13.1.8, as appropriate.
